

**CLAIMS**

What is claimed is:

1. A method of transferring data between a host and a network, the method comprising:

5 providing a plurality of data transfer queues in a shared memory, the individual data transfer queues comprising a priority level and one or more entries, the individual entries being associated with data to be transferred between the host and the network, wherein a first data transfer queue has a higher priority level than a second data transfer queue; and

10 transferring data between the host and the network by transferring data associated with entries of the first data transfer queue before transferring data associated with entries of the second data transfer queue.

2. The method of claim 1, wherein each of the data transfer queues has a  
15 unique priority level, and wherein transferring data between the host and the network comprises transferring data associated with entries of a particular data transfer queue only after all data associated with entries of higher priority data transfer queues has been transferred.

20 3. The method of claim 2:  
wherein providing the plurality of data transfer queues comprises providing a plurality of receive descriptor rings in the shared memory, the individual receive descriptor rings comprising a unique priority level and one or more receive descriptors, the receive descriptors being associated with one or more data frames received from the  
25 network that are to be transferred to the host; and

wherein transferring data between the host and the network comprises transferring one or more data frames associated with one or more receive descriptors of a particular receive descriptor ring only after all data associated with receive descriptors of higher priority receive descriptor rings has been transferred.

30

4. The method of claim 1, wherein each of the data transfer queues has a unique priority level, and wherein transferring data between the host and the network comprises:

5 determining a number of data frames associated with entries of data transfer queues of a higher priority than a particular data transfer queue that have been transferred while the particular data transfer queue was requesting service; and

transferring data associated with entries of a particular data transfer queue if all data associated with entries of higher priority data transfer queues has been transferred or if the number is greater than or equal to a threshold value associated with the particular  
10 data transfer queue.

5. The method of claim 4, wherein determining the number of data frames associated with entries of data transfer queues of a higher priority comprises:

15 providing individual counters for all but a highest priority data transfer queue;  
providing a threshold value for a particular data transfer queue;

clearing a counter for the particular data transfer queue when data associated with an entry of the particular queue is transferred between the host and the network; and

incrementing the counter for the particular data transfer queue when the particular data transfer queue is requesting service and a data frame associated with an entry of a  
20 higher priority data transfer queue is transferred between the host and the network.

6. The method of claim 5, wherein threshold values for different data transfer queues are different.

25 7. The method of claim 5:

wherein providing the plurality of data transfer queues comprises providing a plurality of transmit descriptor rings in the shared memory, the individual transmit descriptor rings comprising a unique priority level and one or more transmit descriptors, the transmit descriptors being associated with one or more data frames received from the  
30 host that are to be transferred to the network; and

H1231

wherein transferring data between the host and the network comprises transferring data associated with transmit descriptors of a particular transmit descriptor ring if all data associated with transmit descriptors of higher priority transmit descriptor rings has been transferred or if the number of data frames associated with entries of data transfer queues  
5 of a higher priority is greater than or equal to a threshold value associated with the particular transmit descriptor ring.

8. The method of claim 4:

wherein providing the plurality of data transfer queues comprises providing a  
10 plurality of transmit descriptor rings in the shared memory, the individual transmit descriptor rings comprising a unique transmit priority level and one or more transmit descriptors, the transmit descriptors being associated with one or more data frames received from the host that are to be transferred to the network; and

wherein transferring data between the host and the network comprises transferring  
15 data associated with transmit descriptors of a particular transmit descriptor ring if all data associated with transmit descriptors of higher transmit priority transmit descriptor rings has been transferred or if the number of data frames associated with entries of data transfer queues of a higher priority is greater than or equal to a threshold value associated with the particular transmit descriptor ring.

20

9. The method of claim 8:

wherein providing the plurality of data transfer queues further comprises providing a plurality of receive descriptor rings in the shared memory, the individual receive descriptor rings comprising a unique receive priority level and one or more  
25 receive descriptors, the receive descriptors being associated with one or more data frames received from the network that are to be transferred to the host; and

wherein transferring data between the host and the network comprises transferring one or more data frames associated with one or more receive descriptors of a particular receive descriptor ring only after all data associated with receive descriptors of higher  
30 receive priority receive descriptor rings has been transferred.

10. The method of claim 1, wherein providing the plurality of data transfer queues comprises:

5 providing a plurality of receive descriptor rings in the shared memory, the individual receive descriptor rings comprising a unique receive priority level and one or more receive descriptors, the receive descriptors being associated with one or more data frames received from the network that are to be transferred to the host, and

10 providing a plurality of transmit descriptor rings in the shared memory, the individual transmit descriptor rings comprising a unique transmit priority level and one or more transmit descriptors, the transmit descriptors being associated with one or more data frames received from the host that are to be transferred to the network; and

wherein transferring data between the host and the network comprises:

15 transferring one or more data frames associated with one or more receive descriptors of a particular receive descriptor ring only after all data associated with receive descriptors of higher receive priority receive descriptor rings has been transferred, and

20 transferring data associated with transmit descriptors of a particular transmit descriptor ring if all data associated with transmit descriptors of higher transmit priority transmit descriptor rings has been transferred or if the number of data frames associated with entries of data transfer queues of a higher priority is greater than or equal to a threshold value associated with the particular transmit descriptor ring.

25

11. The method of claim 1, further comprising providing an entry to a particular data transfer queue according to the data associated with the entry.

30 12. A system for transferring data between a host and a network using a shared memory, the system comprising:

a plurality of data transfer queues in a shared memory, the individual data transfer queues comprising one or more entries, and the individual entries being associated with data to be transferred between the host and the network; and

5 a network interface system coupled with the shared memory, the host, and the network, the network interface comprising a descriptor management system storing a plurality of priority levels, the priority levels being individually associated with one of the data transfer queues, wherein a first data transfer queue has a higher priority level than a second data transfer queue, and wherein the network interface system transfers data between the host and the network by transferring data associated with entries of the first  
10 data transfer queue before transferring data associated with entries of the second data transfer queue.

13. The system of claim 12, wherein each of the data transfer queues has a unique priority level.  
15

14. The system of claim 13, wherein the plurality of data transfer queues comprises a plurality of receive descriptor rings in the shared memory, the individual receive descriptor rings comprising a unique receive priority level and one or more receive descriptors, the receive descriptors being associated with one or more data frames  
20 received from the network that are to be transferred to the host, and wherein the descriptor management system provides a receive descriptor to a particular receive descriptor ring according to the data associated with the receive descriptor.

15. The system of claim 13, wherein the plurality of data transfer queues  
25 comprises a plurality of receive descriptor rings in the shared memory, the individual receive descriptor rings comprising a unique receive priority level and one or more receive descriptors, the receive descriptors being associated with one or more data frames received from the network that are to be transferred to the host, and wherein the host reads one or more data frames from the shared memory that are associated with one or  
30 more receive descriptors of a particular receive descriptor ring only after all data

H1231

associated with receive descriptors of higher priority receive descriptor rings has been read from the shared memory.

16. The system of claim 12:

5 wherein the plurality of data transfer queues comprises a plurality of transmit descriptor rings in the shared memory, the individual transmit descriptor rings comprising a unique transmit priority level and one or more transmit descriptors, the transmit descriptors being associated with one or more data frames received from the host that are to be transferred to the network;

10 wherein the descriptor management system comprises a plurality of counters individually corresponding to all but a highest priority transmit descriptor ring;

wherein the network interface system transfers data associated with transmit descriptors of a particular transmit descriptor ring from the shared memory to the network if all data associated with transmit descriptors of higher priority transmit descriptor rings  
15 has been transferred or if a value of a counter corresponding to the particular transmit descriptor ring is greater than or equal to a threshold value associated with the particular transmit descriptor ring;

wherein the descriptor management unit clears the counter for the particular transmit descriptor ring when data associated with a transmit descriptor of the particular  
20 transmit descriptor ring is transferred from the shared memory to the network; and

wherein the descriptor management unit increments the counter for the particular transmit descriptor ring when a data frame associated with a transmit descriptor of a higher priority transmit descriptor ring is transferred from the shared memory to the network.

25

17. The system of claim 16, wherein the host provides a plurality of threshold values to the descriptor management system, the threshold values individually corresponding to all but the highest priority transmit descriptor ring.

18. The system of claim 16, wherein the host provides data to the shared memory and provides a corresponding transmit descriptor to a particular transmit descriptor ring according to a desired transmit priority for the data.

5 19. The system of claim 16, wherein the plurality of data transfer queues further comprises a plurality of receive descriptor rings in the shared memory, the individual receive descriptor rings comprising a unique receive priority level and one or more receive descriptors, the receive descriptors being associated with one or more data frames received from the network that are to be transferred to the host, and wherein the  
10 host reads one or more data frames from the shared memory that are associated with one or more receive descriptors of a particular receive descriptor ring only after all data associated with receive descriptors of higher priority receive descriptor rings has been read from the shared memory.

15 20. A network interface system for interfacing a host with a network, the system comprising:  
a descriptor management system storing a plurality of priority levels, the priority levels being individually associated with a data transfer queue in a shared memory, wherein a first data transfer queue has a higher priority level than a second data transfer  
20 queue, and wherein the network interface system transfers data between the host and the network by transferring data associated with entries of the first data transfer queue before transferring data associated with entries of the second data transfer queue.

21. The system of claim 20, wherein each of the data transfer queues has a  
25 unique priority level.

22. The system of claim 21, wherein the plurality of data transfer queues comprises a plurality of receive descriptor rings in the shared memory, the individual receive descriptor rings corresponding to a unique receive priority level and comprising  
30 one or more receive descriptors, the receive descriptors being associated with one or more

H1231

data frames received from the network that are to be transferred to the host, and wherein the descriptor management system provides a receive descriptor to a particular receive descriptor ring according to the data associated with the receive descriptor.

5           23.     The system of claim 20:

          wherein the plurality of data transfer queues comprises a plurality of transmit descriptor rings in the shared memory, the individual transmit descriptor rings comprising a unique transmit priority level and one or more transmit descriptors, the transmit descriptors being associated with one or more data frames received from the host that are  
10   to be transferred to the network;

          wherein the descriptor management system comprises a plurality of counters individually corresponding to all but a highest priority transmit descriptor ring;

          wherein the network interface system transfers data associated with transmit descriptors of a particular transmit descriptor ring from the shared memory to the network  
15   if all data associated with transmit descriptors of higher priority transmit descriptor rings has been transferred or if a value of a counter corresponding to the particular transmit descriptor ring is greater than or equal to a threshold value associated with the particular transmit descriptor ring;

          wherein the descriptor management unit clears the counter for the particular  
20   transmit descriptor ring when data associated with a transmit descriptor of the particular transmit descriptor ring is transferred from the shared memory to the network; and

          wherein the descriptor management unit increments the counter for the particular transmit descriptor ring when a data frame associated with a transmit descriptor of a higher priority transmit descriptor ring is transferred from the shared memory to the  
25   network.
